

ALA-1

1.explanation

Solution:-

Error 1: qty is a string

When you use input (), Python stores the value as text. You cannot multiply text with numbers for calculations.

Solution: Convert the input into an integer using int ().

Wrong:

```
qty = input("Enter quantity: ")
```

Correct:

```
qty = int(input("Enter quantity: "))
```

Error 2: Missing colon after if

Python requires a colon at the end of if, else, and for statements. Without it, you get a syntax error.

Wrong:

```
if total > 3000
```

Correct:

```
if total > 3000:
```

Error 3: Indentation problem

Python uses indentation to define blocks of code. The lines inside if or else must be indented.

Wrong:

```
if total > 3000:  
discount = total * 0.1
```

Correct:

```
if total > 3000:  
    discount = total * 0.1
```

Error 4: Wrong variable name

Python is case sensitive. total and Total are different variables.

Wrong:

```
print("Total:", Total)
```

Correct:

```
print("Total:", total)
```

Error 5: Missing colon in for loop

The for loop also requires a colon at the end.

Wrong:

```
for i in range (3)
```

Correct:

```
for i in range (3):
```

Error 6: Service not in list

If the user enters a service name that is not in the list, the program will crash with an error.

Solution: Check if the service exists in the list before using index ().

Correct approach:

```
if service in services:
```
